

Comparing models on the same match situations

16 matches · 38,035 match situations · 752 successful penetrations · Same situations for every model

Every model uses the same outcome, match-based cross-validation and top-10% review budget.

These matches were used for model development. Results are retrospective; this is not an independent test.

AUC: probability a positive state ranks above a negative state; 0.5 = chance (half credit for ties).

What the SOG feature block receives

Context baseline (M0)	Ball location, possession age, pressure, player speeds, defensive geometry and current control.
Scalar SOG summary	Mean of the highest-scoring 10% of valid hypothetical movements.
SOG landscape	Score sizes, distribution, leading-score gap and concentration across players.
Movement alignment	Whether attackers are moving toward their own highest-scoring directions.

SOG algorithm: $S(a) = \frac{\sum (1 - C_0(r)) [C_a(r) - C_0(r)]_+}{\rho_a / (1 \text{ m})}$; rank candidate movements by decreasing score.

C_0 : baseline attacking control; C_a : control after movement a ; ρ_a : displacement; $[z]_+ = \max(z, 0)$. Interval: 95% paired match bootstrap.
